Abstract

Problem and Purpose: Depression is the most common symptom in Multiple Sclerosis (MS) patients with reported lifetime prevalence of 25-50%. Undetected and untreated depression in MS patients has been associated with poor psycho-social and treatment outcomes. Early detection and management of depression has been shown to ameliorate those negative outcomes and improve quality of life. Time constraints in ambulatory clinic settings can impact providers' ability to perform a thorough psychological as well as physical evaluation. To address this gap adoption of a standardized depression screening tool in the care of MS patients was an important opportunity to address a critical need and improve quality of patient care. The purpose of this quality improvement (QI) project was to implement and evaluate the effectiveness of a Depression Screening Program in adult ambulatory outpatient neurology clinic with MS patients using the Patient Health Questionnaire (PHQ-9) screening tool.

Methods: The primary aim of this QI project was to implement a depression screening protocols for adult MS patients in an outpatient neurology clinic using the Patient Health Questionnaire-9 (PHQ-9), a validated depression screening instrument. Medical assistants (MAs) completed the PHQ-9 with patients during telemedicine visits. The MS providers reviewed and provided brief intervention and referrals if warranted. The project leader mobilized a site team, trained MS providers and MAs, mentored champions, tracked the project on a weekly basis, and provided the staff with weekly data updates.

Results: PHQ-9 tool was utilized for depression screening in 144 out of 149 patients who had health visits during the 13-week period (97% compliance). Out those of 144 patients who were screened, 50% (n=72) were positive (PHQ-9 scores 5-27) for depression. 100% (n= 144) PHQ-9 scores were discussed and reviewed by MS providers. The treatment and referrals contributed to,

27.7% of patients were prescribed antidepressant, 12.5% were referred to mental health providers. One patient had suicidal ideation, necessitating an urgent transfer to the emergency department (ED).

Conclusion: Depression screening program using the PHQ-9 was adopted by the neurology clinic for MS patients. This program was able to identify depression in adult MS patients and facilitate treatment or referral to mental health providers. Early detection, treatment, or referral of adult MS patients with depression may help prevent ED visit or hospitalizations and will improve the quality of life for these patients.

Introduction

Multiple Sclerosis (MS) is the most common chronic, non-traumatic neurological disorder among young adults with onset usually occurring between 20-50 years. According to the National Multiple Sclerosis Society (2019), it is estimated that 2.3 million people suffer from MS worldwide and nearly 1 million are living with MS in the United States, making it the most common autoimmune disease of the nervous system (Encarnacao et al., 2018). MS is manifested by a prodrome of symptoms including impaired mobility, fatigue, pain, depression, anxiety, cognitive impairment, sexual dysfunction, bowel/bladder dysfunctions, vision and hearing problems, seizure, and spasticity, which can be short or/long lasting or permanent.

Depression is the most common symptom in MS patients with reported lifetime depression-prevalence of 25-50%, which is higher than the 12.9% lifetime prevalence among patients with other chronic medical conditions (Ferrando et al., 2007; Patrick et al., 2019). Depression is also a predictor of suicidality in people with MS. Suicide is an important cause of death in MS due to uncontrolled depression (Viner et al., 2013). The lifetime suicidal intent is 29% and lifetime suicide attempt rate is 6.4% (Qiuyan et al., 2019). Undetected and untreated depression in individuals with MS has been associated with poor psycho-social and treatment outcomes such as anxiety, fatigue, pain, sleep disturbances, cognitive dysfunction, poorer quality of life, restricted social and economic opportunities, reduced medication adherence, MS symptoms exacerbation, and increased risk of suicide (Fragoso et al., 2014; Kiropoulos et al., 2020). Early detection, diagnosis, and treatment of depression in MS patients has been shown to ameliorate those negative outcomes and improve their quality of life (Boeschoten et al., 2017; Marrie et al., 2017).

Time constraints in ambulatory clinic settings can impact providers' ability to perform a thorough psychological as well as physical evaluation. The American Academy of Neurology (2014) recommends formal depression screening for the MS patient at least once every 12 months. The Joint Commission (TJC) and Centers for Medicare and Medicaid Services (CMS) have also affirmed the assessment of depression as an important clinical indicator for health care quality. The director of the MS Center was supportive of implementing a screening program to determine if MS patients were experiencing depression, possibly as an early diagnosis, and if detected, to facilitate management of depression for adult MS patients. To address the lack of a depression screening protocol in an Ambulatory Neurology Clinic, a neuroscience nurse practitioner (NP) identified strategies to improve this clinical practice with the implementation of program that would train providers to utilize standardized depression screening tool for all MS patients. The purpose of this quality improvement (QI) project was therefore implementation and evaluation of a Depression Screening Program in adult MS patients using the Patient Health Questionnaire (PHQ-9) screening tool which aims to assist providers to screen and detect depression and then provide interventions and referrals as warranted.

Evidence Review

Seven studies were included in this literature review including two systematic reviews, two meta-analyses, two perspectives, and one cross sectional study. All seven studies reported strong evidence for using the PHQ-9 screening tool in an outpatient, non-psychiatric setting with an emphasis on screening MS patients for depression. The literature review provided evidence about using a validated tool such as the PHQ-9 with MS patients. Three main themes were reviewed in these articles: depression risk in MS patients and associated adverse effects, screening of depression using PHQ-9, and brief interventions and/or referrals to mental health

providers. All studies concluded that, screening and brief interventions and/or referrals, to mental health providers for depression in adult MS patients in the outpatient setting improves patients' outcomes (Appendix A).

Two systematic reviews highlighted similar designs, sample sizes, settings, methods, and results emphasizing the importance of screening MS patients for depression. Patrick et al., 2019; Hind et al., 2015 compared the PHQ-9 to the PHQ-2 and found no significant difference between the level of depression identified with each questionnaire. Hind et al., (2015) recommended the PHQ-2 because it is quick, easy to administer, and not overlapping with the MS symptoms. Marrie et al., (2018) supported those findings as well. They also suggested that the higher cut-off points of the PHQ-9 are due to potential overlap of MS symptoms with somatic symptoms of depression. In contrast, Sjonnesen et al., (2012) found that MS symptoms did not invalidate the interpretation of the PHQ-9 when used in patients with MS. These items did not appear to make any substantial difference in the scale's performance in patients with MS when comparisons were made with the general population.

Researchers also found that the risks of attempted and completed suicide were 10 times greater among patients reporting elevated PHQ-9 item-9 scores and increased with persistence of the elevated scores (Dickstein et al., 2015). Additionally, Qiuyan et al., (2019) performed a meta-analysis included data from 260,752 MS patients and found that the association between suicide and multiple sclerosis was statistically significant with a suicide rate ratio (SRR) of 1.71 (95% CI 1.37 to 2.15). They also found that risk of suicide at diagnosis of multiple sclerosis (SRR 2.12, 95% CI 1.84 -2.46) was higher than the risk of suicide at symptom onset (SRR 1.69, 95% CI 1.43-2.00). In contrast, the PHQ-2 is missing an important item that assesses for suicide. The PHQ-9 is a depression self-report instrument and was developed using the domains of the DSM-

IV criteria for depression reflecting the patient's mood in the previous two weeks (Hind et al., 2016; Pattern et al., 2015; Patrick et al., 2019).

The PHQ-9 is considered a valid and reliable tool with sound psychometrics for assessing depression in MS patients (scores >10, had sensitivity 88%, specificity 88%, positive likelihood ratio of 10.12 (95% CI 6.52-15.67) and negative likelihood ratio (0.22.CI 0.15 to 0.32) (Patrick et al., 2019; Patten et al, 2015). Internal validity was strong with a Cronbach's α of 0.89 (Hind et al., 2016; Patrick et al., 2019). The PHQ-9 can be completed by self-report or administered by the clinician in the clinic or via telephone (Hind et al., 2016; Patrick et al., 2019). It may be scored categorically to diagnose major depressive and subclinical depressive disorders, or it may be used as a continuous numerical measure to assess and track severity of depressive symptoms over time (Pattern et al., 2015).

Overall, the studies included in this literature reviews were relevant to the target population of this project. Furthermore, each study applied the PHQ-9 as a screening tool. All the studies had statistically significant findings, regarding sensitivity, specificity, reliability, and validity of the PHQ-9 and /or the effects screening for depression on patients' outcomes.

Theoretical Framework

Kurt Lewin's Change Theory (1947) was utilized to guide this QI project. Change is an essential component of nursing practice. Major change is always a challenge for nurse leaders. In 1947, a pioneer in the study of Group Dynamics Kurt Lewin theorized a three-stage model of change (unfreezing-change-refreezing) to identify and examine the factors and forces that influence a situation. At the beginning stage, individuals must be given assistance to overcome resistance in giving up the old behavior (Lewin, 1947). The second stage involves changing thoughts, feelings, and/or behaviors of individuals is considered to be most difficult, because of

uncertainty and fear associated with change (Shirey, 2013). The last stage, also called refreezing, is establishing the change as a new habit and is a necessary component of this theory in order to see whether change has been implemented is retained. Lewin also describes behavior as “a dynamic balance of forces working in opposing directions” (Shirey, 2013, p.1). Driving forces facilitate the change to occur from the status quo. On the other hand, restraining forces are those that counter the driving force and hinder the change.

During the Unfreezing stage, project manager and change champion helped other MS providers in recognizing and understanding why there was a need for screening and providing support for depression in multiple sclerosis patients. There was a lack of guidelines for depression screening and management in this facility, therefore, the driving force had to be applied to unfreeze the behavior. In the change stage, MS providers were provided opportunities to discuss any barrier to the practice change. Any patient outcomes were shared with clinic site advisor and MS providers during staff meetings to underscore the need for this change. MS providers were encouraged regularly to make this practice change. The third phase involved implementation of screening program for MS patients, in this case, establishing a new behavior that was expected to be permanent. With feedback from the MS providers, and the continuous support from the change champions to using this screening tool, restraining forces were anticipated to minimized, thereby the driving forces facilitated this program to be adopted by the providers.

Methods

The practice change was implemented in an Outpatient Neurology Clinic in the Mid-Atlantic region. There were three MS attending physicians, one MS NP (project leader), and four Medical Assistants (MAs), who were seeing adult MS patients via telemedicine visits. Inclusion

criteria for these visits included: patients diagnosed with MS according to the McDonalds criteria's, age > 18 years, English speaking, and not severely cognitive and physically impaired. Exclusion criteria included: no other neurological disease, non-English speaking, severely impaired cognitively or physically, deaf, clinically diagnosed with depression or currently taking anti-depressant medications. MAs completed the PHQ-9 with the patients during their tele-visit time (Appendix D and E: PHQ-9 Instrument and Scoring Classifications). MS provider reviewed the PHQ-9 scores and did an in-depth clinical evaluation during same visit to confirm the diagnosis (Appendix E). A procedure was in place if the patient verbalized suicidal ideations. This included notifying the behavioral crisis team immediately to evaluate the patient.

During implementation period, the structure measures were policy and procedure for depression screening for MS patients implementing PHQ-9 screening tool and training of staffs on PHQ-9. Process measures included the number of the eligible MS outpatients who received and completed the screening tool, the number of MS patients with positive depression scores who were offered intervention and/or referral to mental health providers. The outcome measures for the intervention were the number of MS patients who initiated new anti-depressant therapy and were adherent to the treatment regimen recommendations. The flowchart in Appendix G was produced by the project leader to simplify and elucidate the depression screening process including management for positive results. All data were entered by the project leader into a Microsoft Excel spreadsheet for further data analysis. A run chart was utilized for data analysis of this QI project. The project leader shared and discussed the run chart with providers during monthly virtual staff meetings to track the progress of the project.

The Project Proposal was submitted for IRB approval to the University of Maryland, Baltimore (UMB) and the project was approved as Non-Human Subject Research. Each week,

the project leader analyzed the de-identified data to see the progress of the project. Data collection tools were used with no identifying information and the files were stored in password-protected computer only accessible by the project leader at the clinical site. Any printed forms were kept safe in a locked cabinet at the clinical site.

Results

This Outpatient Neurology Clinic was successful in changing the major structures and process to implement this QI project. Prior to implementation, three MS providers and four MAs were educated and trained by the project leader about administering, interpreting, and documenting the results of when screening using the PHQ-9 depression screening tool, in the electronic medical record. A lesson plan was used for this training. (See Appendix B). To measure the competency of the trainees on the PHQ-9, System Usability Scale (SUS), a modified form of Likert Scale, was used (Appendix C). Their overall score was 98/100 (score at or above 68/100 is acceptable on SUS scale).

Over the 13 week of implementation period, a total of 149 patients were eligible for depression screening. Of those, 144 were screened using the PHQ-9. The scores were documented in the respective visit notes (97% compliance). Refer to Appendix: I. Out of 144 patients screened, 50% (n=72) were positive (PHQ-9 scores: 5-27) for depression. Among those with depression, 59.72% (n=43) had mild depression, 27.77% (n=20) had moderate depression, and 12.5% (n=9) had severe depression (Appendix J). The treatment and referrals contributed to, 27.7% of patients were prescribed antidepressant, 12.5% were referred to mental health providers (Appendix J). One patient had suicidal ideation, necessitating an urgent transfer to the Emergency Department (ED).

Project outcomes were affected by facilitators and barriers. One of the strongest facilitators for the success of this project was the MS Center Director's wholehearted support of this project. The presence of a project champion who supported MS providers and clinic staffs to use the screening tool in the implementation period was another strong facilitator of this project. The PHQ-9 tool was an additional facilitator. All MS providers were knowledgeable about the strong validity and reliability of the tool which affirmed its use in this project. Furthermore, the incorporation of the PHQ-9 tool into the EMR before the start of implementation enhanced the success of this project. Depression scores were already populated in the visit note following the screening that was conducted by MAs during triage. This saved providers' time in the decision process about management of depression if warranted. Lastly, there were no costs for the screening. The main barrier at the beginning of the project was encountered with the MS providers, who reported time constraints and additional workload during telemedicine patient visits within assigned time-period. These barriers were discussed in detail during monthly staff meeting with the team and acceptable solutions were determined that facilitated overcoming barriers. The run chart also showed the effect of those barriers on the screening compliance when depression screening was done only by the providers. Unfortunately, we were unable to increase the total visit time allowed with each patient. However, we then changed our screening methods by allowing the MAs to do the initial depression screening while triaging the patients. As a result, our screening compliance reached nearly 100%. Additionally, the project leader was in the clinic once a week to check in with project champions to observe the compliance of screening and provide in person help if needed.

Discussion

Implementation of depression screening program using the PHQ-9 tool fostered 72 MS patients who tested positive for depression to receive mental health support. It was anticipated that 100% of the time MS providers would review patients' PHQ-9 scores during the 13 weeks of implementation, and this outcome was successfully met. Ideally, 100% of MS patients would have been screened for depression each week during implementation, but this goal was not met due to time constraints. The project manager and clinical site advisor (CSA) identified the alternative ways to reduce time burden for the providers. The MAs were trained, and they then screened patient's during their telehealth visits. Additionally, the project manager sent out reminders thorough e-mail, doc halo, and sometimes in person to MAs to screen patients to meet the goal (100% compliance). Twenty-eight percent of MS patients (n=20) were started on anti-depressant medications and 13% (n=9) were referred to mental health providers. This practice change facilitated MS patients to discuss their signs/symptoms of depression and who then received mental health support to improve their quality of life. Out of the 144 patients, 72 patients (50%) were positive for depression. This finding was consistent with the literature across the United States as well as internationally (Boeschoten et al.,2017., Ferrando et al.,2007., Marrie et al., 2017; Patrick et al.,2019). The range of PHQ-9 scores in this project were similar to those found by Hinder al., 2016; Patrick et al.,2019, indicating that most patients have minimal depression (PHQ-9 scores 5-10) and no proposed treatment actions. One patient had suicidal ideation, necessitating an urgent transfer to the emergency department (ED). This finding was also consistent with conclusions found in the literature review (Qiuyan et al., 2019; Viner et al., 2013). Clinicians should become skilled at screening and assessing for suicidal risk in MS patients, because screening for suicide could be a crucial step to preventing suicide and ultimately saving lives.

The spread of the findings is also limited; Since this project was targeted specifically to MS patients at a neurology outpatient setting, the implementation process and the results are not generalizable to other settings but can offer guidance for similar implementation project. Additionally, this project had a limited timeframe for implementation; A longer implementation period would be required to assess the impact of the of the depression screening on preventing ED visits or hospitalizations and impact on quality of life.

Conclusion

The prevalence of depression in MS patients is remarkably high and if not diagnosed and treated could lead to detrimental outcomes. This QI project found that depression screening using the PHQ-9 tool is a cost-effective, user friendly, and time-efficient approach to identifying depression in adult MS patients and ensuring subsequent treatment or referrals to mental providers. This project is beneficial, and the results illustrate the significance of project sustainability. The sustainability of this project is dependent on the MS providers' adherence and support to continuing the screening process, after this initial implementation period. Additionally, it will be important to identify a clinic champion who will continue to support MS providers and clinic staff to use the screening tool in the post-implementation period. Furthermore, the structure change of placing the PHQ-9 into the provider note within the electronic health record gives this project the opportunity for sustainability. The PHQ-9 screening results are now in a flow sheet that providers see every time they open patient's encounter. A challenge to sustainability is that a process was not built into the practice to support reminders for the MS providers to improve documentation compliance. A future QI project is needed to build in these important structural changes. Another future project to help with sustainability includes spreading implementation of the depression screening tool in other busy

subspecialty clinics within the organization. In conclusion, when providers are trained and use a standardized depression screening tool for MS patients, early detection, treatment, or referrals for mental health support may improve quality of life.

					<p>concentration (0.55) subscales.</p> <p>Conclusion: All instruments identified in this review need further work on validation and reliability for use in people with MS. Based on the available evidence regarding these measures, researchers and practitioners are faced with trade-offs depending on their priorities. In addition, researchers conducting further studies need to pay special attention to the contamination of the depression inventory scores overlapping with the MS symptoms. However, it may be that a strategic re-evaluation is required in the approach to measuring depression in people with MS. Rather than researchers pursuing a piecemeal approach to specific psychometric properties of a range of outcome an alternative might be to move towards constructing and adopting Quality of</p>

<p>“To synthesize published findings on the psychometric properties of the 9-item Patient Health Questionnaire (PHQ-9) when applied to people with multiple sclerosis (pwMS).”</p>	<p>Systematic Review</p>	<p>Search Strategy: Electronic searches via evidence were gathered from the databases ‘PubMed’, ‘Medline’ and ‘ISI Web of Science’, supplemented by hand-searching of references from all eligible sources. Search terms used were ‘Multiple Sclerosis’ ‘PHQ-9’, and the related terms (‘MS’, ‘Disseminated Sclerosis’, ‘PHQ Patient Health Questionnaire’, ‘Patient Health Questionnaire 9’, ‘PRIME-MD’). Included studies were published between 2012 and 2017 by research groups based in the USA (n = 4) and Canada (n = 3) Eligible Studies: Primary literature written in English and published following peer-review with a primary aim to evaluate the performance of the PHQ-9 in pwMS Included: 7 articles were included related MS and PHQ-9. Prisma: Included detailing criteria for</p>	<p>Eight performance indicators were measured to evaluate performance of the pHQ-9 in pwMS: Appropriateness was defined by identification of whether the PHQ-9 was being tested as a screening, diagnostic, or monitoring tool for depression/suicidality in pwMS. Reliability was defined by evaluation of internal (e.g., split-half / Cronbach’s alpha) and external measures (test-retest). Validity was defined based on criterion, concurrent and discriminant approaches. Studies that attempted to define the dimensionality of the PHQ-9 were also interpreted to represent validity studies for the underlying constructs of depression and suicidality. Responsiveness was defined as a determination of QOL change and/or therapeutic response. Precision was defined as exploration of</p>	<p>Dependent Variable: Quality of life. Measure: Quality of life was measured with SF-36. These scales are further combined into 2 scales: a physical component summary score (PCS), which contains information about physical health status (PHS), and a mental component summary score (MCS), which informs about mental health status (MHS). All item scores are transformed into a scale from 0 (poor health) to 100 (optimal health). Cronbach’s alphas for the summary scores were 0.87 for PCS and 0.78 for MCS in PD patients, and 0.89 for PCS and 0.89 MCS for patients with MS. alternative scoring paradigms and evaluation of their relative utility. Interpretability of scores was defined as using ecological validation approaches and/or relationships to QOL or other depression indicators. Acceptability was defined as the</p>	<p>Seven relevant studies were identified, these were of high quality and included 5080 participants from all strong evidence was found supporting the validity of the PHQ-9 as a unidimensional measure of depression. Used as a screening tool for major depressive disorder (MDD) with a cut-point of 11, sensitivity was 95% sensitivity and specificity 88.3% (PPV 51.4%, NPV 48.6%). Alternative scoring systems that may address the issue of overlap between somatic features of depression and features of MS per se are being developed, although their utility remains unclear. However, data on reliability was limited, and no specific evidence was available on test-retest reliability, responsiveness, acceptability, or feasibility. Conclusions: The PHQ-9 represents a suitable tool to screen for MDD in pwMS. However, use as a</p>

Rating System for Hierarchy of Evidence

Level of Evidence	Type of Evidence
I (1)	Evidence from systematic review, meta-analysis of randomized controlled trials (RCTs), or practice-guidelines based on systematic review of RCTs.
II (2)	Evidence obtained from well-designed RCT and/or reports of expert committees.
III (3)	Evidence obtained from well-designed controlled trials without randomization.
IV (4)	Evidence from well-designed case-control and cohort studies
V (5)	Evidence from systematic reviews of descriptive and qualitative study
VI (6)	Evidence from a single descriptive or qualitative study
VII (7)	Evidence from the opinion of authorities

University of Maryland School of Nursing
Synthesis Table

Evidence Based Practice Question (PICO): Does implementation of depression screening tool (PHQ-9) and in adult Multiple Sclerosis patients to improve health-related quality of life compared to no screening?			
Level of Evidence	# of Studies	Summary of Findings	Overall Quality
I	3	<p>Hind et al., (2016) conducted a meta-analysis to determine the validity and reliability of self-report depression inventories in multiple sclerosis (MS) patients. Authors found that the reliability of the PHQ-9 ($n=2$), internal consistency was good ($\alpha=0.82$ with inter-item correlations of 0.35–0.67 (moderate to acceptable; item-total correlations were good for anhedonia (0.71), acceptable for depressed mood (0.65), and moderate for fatigue (0.57) and concentration (0.55) subscales.</p> <p>Patrick et al., (2019) conducted a systematic review to evaluate the psychometric properties of the 9-item Patient Health Questionnaires (PHQ-9) in MS patients. Study results support a cut-off score 11 on the depression screening yielded maximal pooled sensitivity (95%) and specificity (88.3%), PPV (51.4%), and NPV (48.6%).</p> <p>Qiuyan et al., (2019) conducted a meta-analysis to evaluate the risk of suicide in multiple sclerosis patients. Author found that the association between suicide and multiple sclerosis was statistically significant with a pooled SRR 1.72 (95%CI 1.48–1.99, I-squared = 55.0%). Risk of suicide at diagnosis of multiple sclerosis (SRR 2.12, 95% CI 1.84–2.46; I-squared = 4.4%) was higher than the risk of suicide at symptom onset (SRR 1.69; 95% CI 1.43–2.00; I-squared = 0.0%).</p> <p>Authors suggested that this meta-analysis should be confirmed and extended in larger studies that consider potential ethnic and geographic factor.</p>	<p>A: Researchers were able to provide a consistent and generalizable review of the literature. Sample size ($n=21$) was adequate for literature review purposes. Selection of research articles and statistical analysis of selected outcome measures were rigorous; comprehensive; and definitive conclusions; and recommendations.</p> <p>A: Well-defined, reproducible search strategies; consistent results with enough numbers of well-defined studies; criteria-based evaluation of overall scientific strength and quality of Included studies and definitive conclusion</p> <p>A: Consistent and generalizable results. Sample size ($n=21$) was adequate. Definitive conclusions and recommendation. Recommendations were aimed at further research.</p>
VI	4	<p>Marrie et al;(2018) aimed to evaluate the validity and reliability of multiple screening measures for depression and anxiety for use in the clinical care of people with MS. In this study authors also mentioned that the PHQ-9 had the</p>	<p>B: No randomization, and no power analysis was reported to contextualize the adequacy of the samples, there is risk for type II error.</p>

	<p>highest sensitivity (84%) ranged from 93.8% to 95% and specificities ranged from 61.2% to 85.9%. However, they suggested that higher cut-points of PHQ-9 scores due to potential overlapping of MS symptoms with somatic symptoms of depression.</p> <p>In contrast, Sjonnesen et al; (2012) found that fatigue and concentration deficits do not invalidate the interpretation of the PHQ-9 when used in patients with MS. These items do not appear to make any substantial difference in the scale's performance in patients with MS when comparisons are made with the general population (odds ratio 2.17, p= 0.025)</p> <p>Viner et al; (2014) found that 21% of the MS patients reported suicidal ideation (suicidal ideation was assessed by using item 9 from the PHQ-9) at least once over the course of the 6 months follow up 95% CI 15.7-28.8). Shorter duration of the study and small sample sizes are the weakness of the study.</p> <p>Dickstein et al; (2015) also support that the 9-item Patient Health Questionnaire (PHQ-9) is a well-validated instrument that is widely used to screen for depression. Item-9 of the questionnaire addresses the presence and persistence of recent thoughts of death or self-harm and has proved useful to screen for suicidal risk in primary care medical settings.</p>	<p>One study (Marrie et al;2018) is cross sectional studies. Weakness of the cross-sectional study, it does not provide with information about changes to the patient over time.</p> <p>One study (Dickstein et al; (2015); Sjonnesen et al; (2012); & Viner et al; (2014)) mentioned that depression, and fatigue are not included in this study. Additionally, most of the patients are treated disease modifying therapies (95%), there is possibility of selection bias. Recommendations were aimed at further research.</p>

Appendix C. Modified System Usability Scale (SUS)

		Strongly disagree			Strongly agree	
		1	2	3	4	5
1	I think that I would like to use this depression screening tool, brief interventions and referral as needed					
2	I found the depression screening, treatment, and referral process was easy to use					
3	I found the depression screening, treatment, and referral process to be unnecessary and time consuming					
4	I think that I would need the support of the project leader to use the depression screening tool					
5	I found the various part of the depression screening, treatment, and referral process were well-integrated into the EMR.					
6	I thought there was too much inconsistency in this depression screening, treatment, and referral processes.					
7	I would imagine that most people would learn to use this depression screening and referral process very quickly.					
8	I found the depression screening, treatment, and referral process very cumbersome to use.					
9	I felt very confident using the depression screening and referral process.					
10	I needed to learn a lot of things before I could get going with his depression screening and referral process.					
Comments:						

Note. Per the Usabilty.gov website, text and documents are public domain, are not copyrighted, and may be copied and distributed if federal branding and loges are removed. This scale was modified from the System Usability Scale, by Usablity.gov. Retrieved from <https://www.usabilty.gov/how-to-and-tools/methods/system-usabiity-sclae.html>.

Using SUS

The SU scale is generally used after the respondent has had an opportunity to use the system being evaluated, but before any debriefing or discussion takes place. Respondents should be asked to record their immediate response to each item, rather than thinking about items for a long time.

All items should be checked. If a respondent feels that they cannot respond to a particular item, they should mark the center point of the scale.

Appendix D. Patient Health Questionnaire-9

Over the last 2 weeks, how often have you been bothered by any of the following problems?	Not at all	Several days	More than half the days	Nearly every day
1. Little interest or pleasure in doing things	0	1	2	3
2. Feeling down, depressed, or hopeless	0	1	2	3
3. Trouble falling or staying asleep, or sleeping too much	0	1	2	3
4. Feeling tired or having little energy	0	1	2	3
5. Poor appetite or overeating	0	1	2	3
6. Feeling bad about yourself – or that you are a failure or have let yourself or your family down	0	1	2	3
7. Trouble concentrating on things, such as reading the newspaper or watching television	0	1	2	3
8. Moving or speaking so slowly that other people could have noticed? Or the opposite – being so fidgety or restless that you have been moving around a lot more than usual	0	1	2	3
9. Thoughts that you would be better off dead or of hurting yourself in some way	0	1	2	3

For office coding: Total Score _____ = _____ + _____ + _____
 Total Score _____

If you checked off any problems, how difficult have these problems made it for you to do your work, take care of things at home, or get along with other people?

Not difficult at all - Somewhat difficult - Very difficult - Extremely difficult

Developed by Drs. Robert L. Spitzer, Janet B.W. Williams, Kurt Kroenke, and colleagues, with an educational grant from Pfizer Inc. No permission required to reproduce, translate, display, or distribute

Appendix E. PHQ-9 Scores and Proposed Treatment Options

PHQ-9 Score	Depression Severity	Proposed Treatment Actions
0-4	None-minimal	None
5-9	Mild	Watchful waiting: repeat PHQ-9 at next follow up
10-14	Moderate	Treatment plan, consider counseling, follow up and /or pharmacotherapy
15-19	Moderately Severe	Active treatment with pharmacotherapy and /or psychotherapy
20-27	Severe	Immediate initiation of pharmacotherapy and, if severe impairment or poor response to therapy, expediated referral to mental health specialist for psychotherapy and /or collaborative management

Developed by Drs. Robert L. Spitzer, Janet B.W. Williams, Kurt Kroenke, and colleagues, with an educational grant from Pfizer Inc. No permission required to reproduce, translate, display, or distribute.

Comments:

Appendix F. Data audit collection tool

Total number of MS patients seen in clinic	The number of patients is eligible for screening	The number of MS patients is screened for depression via PHQ-9	The number of patients with positive score (PHQ-9 >5) who are treated by MS providers	The number of patients with positive score (PHQ-9 >5) who are referred to mental health providers	Weekly mean depression screening score

Appendix I. Results

Appendix J. Results

Appendix K. Patient Educational Handout Facts about Depression in MS patients:

- Depression is very common. Millions of people are suffering from depression in the United States.
- Depression is common among patients with MS. About 25-50 % of MS patients have depression.
- Undiagnosed and untreated depression in individuals with MS has been associated with increased anxiety, fatigue, pain, sleep disturbances, cognitive dysfunction, and poorer quality of life.
- Some MS medications and steroids can make depression symptoms.

Some common signs and symptoms of depression include:

- Feeling sad or irritable most of the day
- Loss of interest or pleasure in activities
- Significant weight loss or gain or a decrease or increase in appetite
- Sleeping too much or being unable to sleep
- Persistent fatigue or loss of energy
- Feeling worthless or guilty with no apparent cause
- Inability to concentrate or make decisions
- Recurrent thoughts of death or suicide

You may have all or only a few of these signs and symptoms. The hallmark of depression is that your symptoms persist, usually lasting at least two weeks.

Get help:

If you are depressed, do not wait to reach out for help. Talk to your primary care provider or a neurologist to determine appropriate next step. Your provider can assist you with your depression or refer you to mental health provider. If you are unable to make appointment with your provider in the next 2 weeks, you can call:

- Mental Health Association of Maryland at 410-235-1178 (www.mhamd.org)
- National Mental Health Association at 1-800-969-6642 (www.nmha.org)

These groups help people with depression or mental health problems.

If you have a thought or plan to hurt yourself or others, please call the following numbers or go to the nearest emergency room ASAP:

- Maryland Crisis Hotline (24/7): 800-422-0009
- Hope line Network (24/7): 800-784-2433
- 911

SAFETY PLAN:

We advise you to abstain from alcohol and other drugs of abuse.
